1 Introduction

This guide covers the usage of PostProc, version 5.3: an open-source package for postprocessing of data produced by PWscf and CP. PostProc is part of the QUANTUM ESPRESSO distribution and requires PWscf to be installed.

This guide assumes that you know the physics that PostProc describes and the methods it implements. It also assumes that you have already installed, or know how to install, QUANTUM ESPRESSO. If not, please read the general User's Guide for QUANTUM ESPRESSO, found in directory Doc/ two levels above the one containing this guide; or consult the web site: http://www.quantum-espresso.org.

Further documentation, beyond what is provided in this guide, can be found in the directory PP/Doc/, containing a copy of this guide. People who want to contribute to QUANTUM ESPRESSO should read the Developer Manual, found in directory Doc/ two levels above the one containing this guide: Doc/developer_man.pdf.

2 People and terms of use

The PostProc package was originally developed by Stefano Baroni, Stefano de Gironcoli, Andrea Dal Corso (SISSA), Paolo Giannozzi (Univ. Udine), and many others. We mention in particular:

- Andrea Benassi (SISSA) for the epsilon utility, Tae Yun Kim and Cheol-Hwan Park (Seoul National University) for fixes to it;
- Dmitry Korotin (Inst. Met. Phys. Ekaterinburg) for the wannier_ham utility;
- Georgy Samsonidze (Bosch Research) for the interface with the Berkeley GW code;
- The late Prof. Eyvaz Isaev for the Fermi Surface code;
- Natalie Holzwarth (WFU) for the PAW projection in code projwfc.f90.

PostProc is free software, released under the GNU General Public License. See: http://www.gnu.org/licenses/old-licenses/gpl-2.0.txt, or the file License in the distribution).

We shall greatly appreciate if scientific work done using this code will contain an explicit acknowledgment and the following reference:

P. Giannozzi, S. Baroni, N. Bonini, M. Calandra, R. Car, C. Cavazzoni, D. Ceresoli, G. L. Chiarotti, M. Cococcioni, I. Dabo, A. Dal Corso, S. Fabris, G. Fratesi, S. de Gironcoli, R. Gebauer, U. Gerstmann, C. Gougoussis, A. Kokalj, M. Lazzeri, L. Martin-Samos, N. Marzari, F. Mauri, R. Mazzarello, S. Paolini, A. Pasquarello, L. Paulatto, C. Sbraccia, S. Scandolo, G. Sclauzero, A. P. Seitsonen, A. Smogunov, P. Umari, R. M. Wentzcovitch, J.Phys.:Condens.Matter 21, 395502 (2009), http://arxiv.org/abs/0906.2569

3 Compilation

PostProc is distributed together with QUANTUM ESPRESSO. For instruction on how to download and compile QUANTUM ESPRESSO, please refer to the general Users' Guide, available in file Doc/user_guide.pdf under the main QUANTUM ESPRESSO directory, or in web site http://www.quantum-espresso.org.

Once QUANTUM ESPRESSO is correctly configured, PostProc can be compiled by just typing make pp, from the main QUANTUM ESPRESSO directory; or typing make from the PP/ subdirectory. Several executable codes are produced in PP/bin and linked to bin/.

4 Usage

All codes for which input documentation is not explicitly mentioned below havesome documentation in the header of the fortran sources. In the following, "Example N" standes for subdirectory examples/exampleN/.

All quantities whose dimensions are not explicitly specified are in RYDBERG ATOMIC UNITS. Charge is "number" charge (i.e. not multiplied by e); potentials are in energy units (i.e. they are multiplied by e).

4.1 Plotting selected quantities

The main postprocessing code pp.x extracts the specified data from the data files produced by PWscf (pw.x executable) or CP (cp.x executable); prepares data for plotting by writing them into formats that can be read by several plotting programs.

Quantities that can be read or calculated are:

charge density spin polarization various potentials local density of states at E_F local density of electronic entropy STM images selected squared wavefunction ELF (electron localization function) RDG (reduced density gradient) integrated local density of states

Various types of plotting (along a line, on a plane, three-dimensional, polar) and output formats (including the popular cube format) can be specified. Moreover data can be saved to an intermediate (formatted) file so that more data set can be summed or subracted in a later run. The output files can be directly read by the free plotting system Gnuplot (1D or 2D plots), or by code plotrho.x that comes with PostProc and produces PostScript 2D plots, or by advanced plotting software XCrySDen and gOpenMol (3D plots).

See file Doc/INPUT_PP.* for a detailed description of the input for code pp.x. See Example 01 for an example of a charge density plot, Example 03 for an example of STM image simulation.

Planar averages Code plan_avg.x calculates planar averages of Kohn-Sham orbitals. Code average.x calculates planar averages of quantities calculated by pp.x (e.g. potentials, charge, magnetization densities). Note that average.x reads the intermediate file produced by pp.x, not data files produced by pw.x. Examples of usage of average.x can be found in examples/WorcFct_ex and in examples/dipole_example/.

All-electron charge pawplot.x produces plots of the all-electron charge for PAW calculations.

About Bader's analysis In http://theory.cm.utexas.edu/henkelman/code/bader/ one can find a software that performs Bader's analysis starting from charge on a regular grid. One should use PAW to compute the charge density. The required "cube" format can be produced using pp.x (info by G. Lapenna who has successfully used this technique, but adds: "Problems occur with polar X-H bonds or in all cases where the zero-flux of density comes too close to atoms described with pseudo-potentials"). This code should perform decomposition into Voronoi polyhedra as well, in place of obsolete code voronoy.x (removed from distribution since v.4.2). Alternatively, you can use CRITIC2, available at https://github.com/aoterodelaroza/critic2, which can read directly pw.x output and "XSF" files. CRITIC2 functionaly include Bader's AIM, ELF, laplacian of density and potentials, non-covalente interaction (NCI) plots and much more.

4.2 Band structure, Fermi surface

The code bands.x reads data file(s), extracts eigenvalues, regroups them into bands (the algorithm used to order bands and to resolve crossings may not work in all circumstances, though). The output is written to a file in a simple format that can be directly read and converted to plottable format by auxiliary code plotband.x. Unpredictable plots may results if k-points are not in sequence along lines, or if two consecutive points are the same. The code bands.x performs as well a symmetry analysis of the band structure. For a complete input description, seeDoc/INPUT_bands.*. See Example 01, Example 04 and Example 06 for simple band plots.

The calculation of Fermi surface can be performed using code fs.x. The resulting file in .bxsf format can be read and plotted using XCrySDen. See Example 02 for an example of Fermi surface visualization (Ni, including the spin-polarized case).

4.3 Projection over atomic states, DOS

The code projwfc.x calculates projections of wavefunctions over atomic orbitals. The atomic wavefunctions are those contained in the pseudopotential file(s). The Löwdin population analysis (similar to Mulliken analysis) is presently implemented. The projected DOS (or PDOS: the DOS projected onto atomic orbitals) can also be calculated and written to file(s). More details on the input data are found in file Doc/INPUT_PROJWFC.*. The ordering of the various angular momentum components (defined in routine flib/ylmr2.f90) is as follows: $P_{0,0}(t)$, $P_{1,0}(t)$, $P_{1,1}(t)cos\phi$, $P_{1,1}(t)sin\phi$, $P_{2,0}(t)$, $P_{2,1}(t)cos\phi$, $P_{2,1}(t)sin\phi$, $P_{2,2}(t)cos2\phi$, $P_{2,2}(t)sin2\phi$ and so on, where $P_{l,m}$ =Legendre Polynomials, $t = cos\theta = z/r$, $\phi = atan(y/x)$.

Data produced by code projwfc.x can be further analysed using auxiliary codes sumpdos.x (sums selected PDOS by specifying the names of files containing the desired PDOS: type sumpdos.x -h or look into the source code for more details) and plotproj.x.

The total electronic DOS can also be calculated by code dos.x, whose complete input documentation is in Doc/INPUT_DOS.* See Example 02 for total and projected electronic DOS calculations; see Example 03 for projected and local DOS calculations.

The DOS projected over *molecular* states (e.g. for a molecule on a surface system) can be computed using code molecularpdos.x (courtesy of Guido Fratesi). See file Doc/INPUT_MOLDOS.* for input documentation and directory MolDos_example/ for an example.

4.4 Wannier functions

There are several Wannier-related utilities in PostProc:

- 1. The "Poor Man Wannier" code pmw.x, to be used in conjunction with DFT+U calculations (see Example 05)
- 2. The interface with Wannier90 code, pw2wannier.x: see the documentation in W90/ (you have to install the Wannier90 plug-in)
- 3. The wannier_ham.x code generates a model Hamiltonian in Wannier functions basis: see examples/WannierHam_example/.

Note that the wfdd.x code has been moved to CP.

4.5 Interfaces to/from other code

Codes pw2bgw.x and bgw2pw.x convert data files from pw.x to a format suitable for usage by the Berkeley GW code, and vice versa. See files Doc/INPUT_pw2bgw.* and Doc/INPUT_bgw2pw.* for input data documentation.

Undocumented code pw2gw.x converts data files from pw.x to a format suitable for usage by another GW code.

Code pw_export.x, not compiled by default, is an interface to other codes, documented in Doc/INPUT_pw_export.* Code qexml.x, not compiled by default, is a template that is useful to follow when wrting interfaces.

4.6 Other tools

Code wfck2r.x converts Kohn-Sham orbitals from reciprocal to real space. It is a useful starting point if you need to access wavefunctions and perform postprocessing operations that are not implemented in QUANTUM ESPRESSO.

Code epsilon.x calculates RPA frequency-dependent complex dielectric function. Documentation is in file Doc/eps_man.tex.

Code initial_state.x calculates the initial state contribution to the Core-level shift. See examples/CLS_IS_example/ for an example, and examples/CLS_FS_example/ for the corrsponding final state calculation of Core-level shifts.

5 Troubleshooting

Almost all problems in QUANTUM ESPRESSO arise from incorrect input data and result in error stops. Error messages should be self-explanatory, but unfortunately this is not always true. If the code issues a warning messages and continues, pay attention to it but do not assume that something is necessarily wrong in your calculation: most warning messages signal harmless problems.

Some postprocessing codes complain that they do not find some files For Linux PC clusters in parallel execution: in at least some versions of MPICH, the current directory is set to the directory where the executable code resides, instead of being set to the directory where the code is executed. This MPICH weirdness may cause unexpected failures in some postprocessing codes that expect a data file in the current directory. Workaround: use symbolic links, or copy the executable to the current directory.

error in davcio in postprocessing codes Most likely you are not reading the correct data files, or you are not following the correct procedure for postprocessing. In parallel execution: if you did not set wf_collect=.true., the number of processors and pools for the phonon run should be the same as for the self-consistent run; all files must be visible to all processors.
